

## Search Insert Position

Since the array is sorted and we need  $O(\log n)$  runtime, we use binary search.

### Algorithm:

1. Initialize  $left = 0$ ,  $right = \text{nums.size()} - 1$ .
2. Perform standard binary search:
  - If  $\text{nums}[mid] == \text{target}$ , return  $mid$ .
  - If  $\text{nums}[mid] < \text{target}$ , move  $left = mid + 1$ .
  - Else move  $right = mid - 1$ .
3. If not found, return  $left$  (correct insertion point).

### Complexity:

- Time:  $O(\log n)$
- Space:  $O(1)$
